

Anonymous3

Final ER Diagram:

Changes made in both requirements doc and ER model :

1. CONTAINS Relation is not included(deleted).

2. Online delivery is not connected to food items, instead it is connected to CUSTOMER.
3. Order number attribute in the delivery apps entity type is removed and delivery id is made as key attribute.

Changes made in ER model document alone:

1. 'ordered items' attribute in order entity type is made composite in the ER model.

Changes made in requirements document alone:

1. Menu is just a multivalued attribute. It is not composite. Funds is only composite.
2. Order number in the customer entity is the latest order number of the customer.

ER model - Relational conversion:

For each regular entity in the ER schema, we created a relation . There are no binary relations of 1:1 relationship type in the data model.

If there is a 1:N binary relationship between S and T:: let S be the entity participating at the N-side of the relationship type. We included as foreign key in S the primary key of the relation T.

Eg: employs, ordered by, takes etc

There are no binary relations of M:N relationship type in the data model.

For each weak entity type W in the ER schema with owner entity type E, we created a relation R, and included all simple attributes of W as attributes of R, plus the primary key of E.

Eg: W=Tables, E=Restaurant

For each multivalued attribute A, we created a new relation R that includes an attribute corresponding to A plus the primary key attribute K (as a foreign key in R) of the relation that represents the entity type or relationship type that has A as an attribute.

eg: Menu, ordered items etc

For each n-ary relationship type $n > 1$, we created a new relation S to represent R. We included as foreign key attributes in S the primary keys of the relations that represent the participating entity types.

Eg: online delivery.

It is in 1st Normal Form

The values in the domain of each attribute are atomic in the Relation schema. It is already in 1st Normal form.

It is in 2nd Normal Form

There are no partial dependencies, because all the tables have single candidate key, except tables which have full dependency. That is, there are no partial dependencies..

3rd Normal Form:

$X \rightarrow Z, Z \rightarrow Y$ where Z is not any key in the relation schema then it violates the 3rd normal form.

TRANSITIVE DEPENDENCY EXISTS:

In Employee entity,

Employee Id \rightarrow Profession \rightarrow Salary ,

Employee Id \rightarrow Profession \rightarrow Employee working hrs

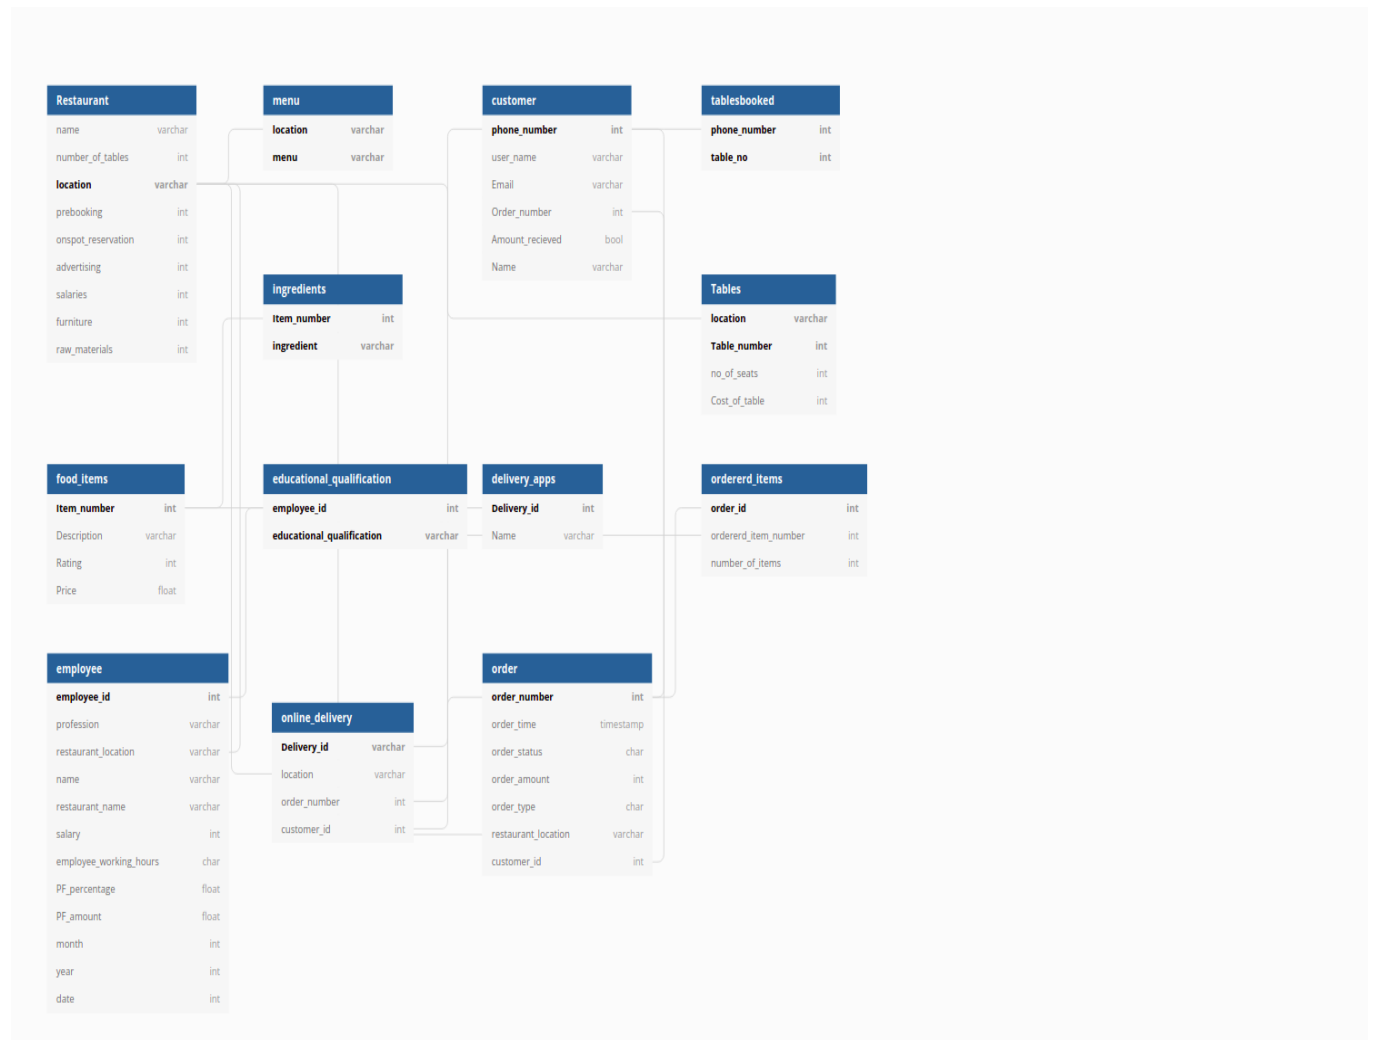

Employee Id \rightarrow Profession \rightarrow PF percentage

Profession is not a key.

So a separate entity Profession is created to make it to 3rd NF.
